"The composite score in @evaluate divides a supplier's reliability by its lead time for the target SKU ..." ...

"The ranking is worked out in @evaluate and passed straight to the model."

@evaluate

pipeline/nodes/evaluate.py:40-74

```
40 def _score_supplier(sup: dict, sku_id: str) -> float:
41     entry = sup["catalog"].get(sku_id, {})
42     lead = entry.get("lead_days", 999)
43     return sup["reliability_score"] / max(lead, 0.1)
44
45
46 def _evaluate_stockout(condition: dict, suppliers: list, llm) -> dict:
47     sku_id = condition["sku_id"]
48     available = [
49         s for s in suppliers
50         if s["availability"] and sku_id in s.get("catalog", {})
51     ]
52     ranked = sorted(available, key=lambda s: _score_supplier(s, sku_id), reverse=True)
53
54     if not ranked:
55         return {
56             "condition": condition,
57             "action": "escalate",
58             "best_supplier": None,
59             "ranked_suppliers": [],
60             "confidence": 0.0,
61             "reasoning": "No available supplier carries this SKU.",
62         }
63
64     ranked_info = [
65         {
66             "supplier_id": s["supplier_id"],
67             "name": s["name"],
68             "score": round(_score_supplier(s, sku_id), 3),
69             "unit_price": s["catalog"][sku_id]["unit_price"],
70             "lead_days": s["catalog"][sku_id]["lead_days"],
71             "reliability": s["reliability_score"],
72         }
73         for s in ranked[:5]
74     ]
```

What it shows: The composite-score function and the ranked-supplier list that becomes the model's main input — the place where a changed score changes the ranking the model sees.
