

@orders — EMA

Appears in: [DL-06](#)

server/routers/orders.py:10, 85-104

"The update fires in @orders the moment an order is marked delivered: the router reads the expected and actual dates, works out the lateness, and updates the supplier's score in place."

@orders — EMA

server/routers/orders.py:10-10

```
10  EMA_ALPHA = 0.2 # new delivery counts 20%, history 80%
```

...

server/routers/orders.py:85-104

```
85  def _apply_ema(order: dict) -> None:
86      supplier = next(
87          (s for s in state.suppliers if s["supplier_id"] == order["supplier_id"]), None
88      )
89      if not supplier:
90          return
91
92      try:
93          expected = datetime.fromisoformat(order["expected_delivery"][:19])
94          actual = datetime.fromisoformat(order["actual_delivery"][:19])
95          lateness = max(0, (actual - expected).days)
96      except Exception:
97          return
98
99      performance = max(0.0, 1.0 - lateness * 0.1)
100     old_score = supplier["reliability_score"]
101     new_score = round(
102         min(1.0, max(0.0, EMA_ALPHA * performance + (1 - EMA_ALPHA) * old_score)), 4
103     )
104     supplier["reliability_score"] = new_score
```

What it shows: `_apply_ema` computes `performance = max(0, 1 - lateness×0.1)` then `new = 0.2·performance + 0.8·old`, rounded to 4 dp — the exact formula DL-06/07 verify.
