

@state — boot reload

Appears in: [DL-06](#)

server/state.py:12-23

"On start-up the state loads both tables back into memory, so the log entries and approvals return exactly as they were before the restart (@state · @db)."

@state — boot reload

server/state.py:12-23

```
12 class AppState:
13     def __init__(self):
14         self._base: dict = {}
15         self._current: dict = {}
16         self.agent_log: list = []
17         self.approvals: list = []
18         self.active_scenario: str = "normal"
19         self.load()
20         from server import db as _db
21         _db.init_db()
22         self.agent_log = _db.load_log_entries()
23         self.approvals = _db.load_all_approvals()
```

What it shows: On construction the state calls `db.init_db()` then reloads `agent_log` and `approvals` from SQLite — the lines that make the queue survive a restart.
